

THE STATE PATTERN

Chandan R. Rupakheti

Week 8-1

Today ...

I thought things in Objectville were going to be so easy, but now every time I turn around there's another change request coming in. I'm at the breaking point! Oh, maybe I should have been going to Betty's Wednesday night patterns group all along. I'm in such a state!

A little-known fact:

The Strategy and State Patterns were twins separated at birth. Strategy changes behavior through interchangeable algorithm whereas State changes behavior by changing an object's internal state.

Jawva Breakers

Java toasters are so '90s. Today people are building Java into *real* devices, like gumball machines. That's right, gumball machines have gone high tech; the major manufacturers have found that by putting CPUs into their machines, they can increase sales, monitor inventory over the network and measure customer satisfaction more accurately.

At least that's their story – I think they just got bored with the circa 1800's technology and needed to find a way to make their jobs more exciting

Manufacturers need your help ...

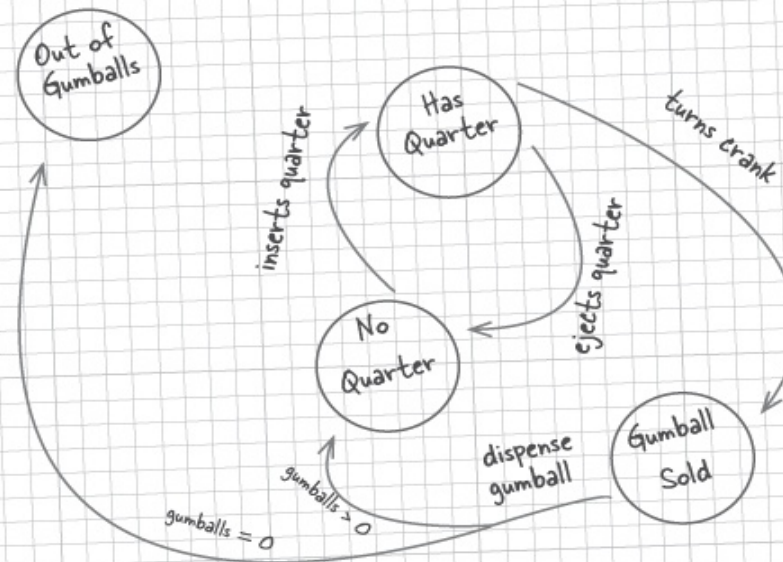

Let's take a look at this diagram and see what the Mighty Gumball guys want...

Here's the way we think the gumball machine controller needs to work. We're hoping you can implement this in Java for us! We may be adding more behavior in the future, so you need to keep the design as flexible and maintainable as possible!

- Mighty Gumball Engineers

State Machines 101

1/3

Let's just call "Out of Gumballs"
"Sold Out" for short.

Variable to hold the
current state

2

```
final static int SOLD_OUT = 0;
final static int NO_QUARTER = 1;
final static int HAS_QUARTER = 2;
final static int SOLD = 3;
```

Gather up states

1

Here's each state represented
as a unique integer...

```
int state = SOLD_OUT;
```

...and here's an instance variable that holds the
current state. We'll go ahead and set it to "Sold
Out" since the machine will be unfilled when it's
first taken out of its box and turned on.

inserts quarter turns crank
ejects quarter
dispense

These actions are
the gumball machine's
interface - the things
you can do with it.

Gather up actions

3

Looking at the diagram, invoking any of
these actions causes a state transition.

Dispense is more of an internal
action the machine invokes on itself.

State Machines 101

2/3

A method for each action

4

```
public void insertQuarter() {

    if (state == HAS_QUARTER) {

        System.out.println("You can't insert another quarter");

    } else if (state == NO_QUARTER) {

        state = HAS_QUARTER;
        System.out.println("You inserted a quarter");

    } else if (state == SOLD_OUT) {

        System.out.println("You can't insert a quarter, the machine is sold out");

    } else if (state == SOLD) {

        System.out.println("Please wait, we're already giving you a gumball");

    }

}
```

Here we're talking about a common technique: modeling state within an object by creating an instance variable to hold the state values and writing conditional code within our methods to handle the various states.

Each possible state is checked with a conditional statement...

...and exhibits the appropriate behavior for each possible state...

...but can also transition to other states, just as depicted in the diagram.

State Machines 101

3/3

```
public class GumballMachine {
```

```
    final static int SOLD_OUT = 0;
    final static int NO_QUARTER = 1;
    final static int HAS_QUARTER = 2;
    final static int SOLD = 3;
```

```
    int state = SOLD_OUT;
    int count = 0;
```

```
    public GumballMachine(int count) {
        this.count = count;
        if (count > 0) {
            state = NO_QUARTER;
        }
    }
}
```

Now we start implementing the actions as methods....

```
    public void insertQuarter() {
        if (state == HAS_QUARTER) {
            System.out.println("You can't insert another quarter");
        } else if (state == NO_QUARTER) {
            state = HAS_QUARTER;
            System.out.println("You inserted a quarter");
        } else if (state == SOLD_OUT) {
            System.out.println("You can't insert a quarter, the machine is sold out");
        } else if (state == SOLD) {
            System.out.println("Please wait, we're already giving you a gumball");
        }
    }
}
```

If the customer just bought a gumball he needs to wait until the transaction is complete before inserting another quarter.

Here are the four states; they match the states in Mighty Gumball's state diagram.

Here's the instance variable that is going to keep track of the current state we're in. We start in the SOLD_OUT state.

We have a second instance variable that keeps track of the number of gumballs in the machine.

The constructor takes an initial inventory of gumballs. If the inventory isn't zero, the machine enters state NO_QUARTER, meaning it is waiting for someone to insert a quarter, otherwise it stays in the SOLD_OUT state.

When a quarter is inserted, if....

...a quarter is already inserted we tell the customer...

...otherwise we accept the quarter and transition to the HAS_QUARTER state.

And if the machine is sold out, we reject the quarter.

In-house Testing

That feels like a nice solid design using a well-thought-out methodology, doesn't it?

```
public class GumballMachineTestDrive {

    public static void main(String[] args) {
        GumballMachine gumballMachine = new GumballMachine(5);

        System.out.println(gumballMachine); // ← Print out the state of the machine.

        gumballMachine.insertQuarter(); // ← Throw a quarter in...
        gumballMachine.turnCrank(); // ← Turn the crank; we should get our gumball.

        System.out.println(gumballMachine); // ← Print out the state of the machine, again.

        gumballMachine.insertQuarter(); // ← Throw a quarter in...
        gumballMachine.ejectQuarter(); // ← Ask for it back.
        gumballMachine.turnCrank(); // ← Turn the crank; we shouldn't get our gumball.

        System.out.println(gumballMachine); // ← Print out the state of the machine, again.

        gumballMachine.insertQuarter(); // ← Throw a quarter in...
        gumballMachine.turnCrank(); // ← Turn the crank; we should get our gumball.
        gumballMachine.insertQuarter(); // ← Throw a quarter in...
        gumballMachine.turnCrank(); // ← Turn the crank; we should get our gumball.
        gumballMachine.ejectQuarter(); // ← Ask for a quarter back we didn't put in.

        System.out.println(gumballMachine); // ← Print out the state of the machine, again.

        gumballMachine.insertQuarter(); // ← Throw TWO quarters in...
        gumballMachine.insertQuarter(); // ← Turn the crank; we should get our gumball.
        gumballMachine.turnCrank(); // ← Now for the stress testing... ☺
        gumballMachine.insertQuarter();
        gumballMachine.turnCrank();

        System.out.println(gumballMachine); // ← Print that machine state one more time.
    }
}
```

Load it up with five gumballs total.

```

```

You knew it was coming... Change Request!

We think that by turning "gumball buying" into a game we can significantly increase our sales. We're going to put one of these stickers on every machine. We're so glad we've got Java in the machines because this is going to be easy, right?

Mighty Gumball, Inc., has loaded your code into their newest machine and their quality assurance experts are putting it through its paces. So far, everything's looking great from their perspective.

In fact, things have gone so smoothly they'd like to take things to the next level...

CEO, Mighty
Gumball, Inc.
JawBreaker or
Gumdrop?

10% of the time,
when the crank
is turned, the
customer gets
two gumballs
instead of one.

The messy STATE of things...

Just because you've written your gumball machine using a well-thought-out methodology doesn't mean it's going to be easy to extend

```
final static int SOLD_OUT = 0;  
final static int NO_QUARTER = 1;  
final static int HAS_QUARTER = 2;  
final static int SOLD = 3;
```

First, you'd have to add a new WINNER state here. That isn't too bad...

```
public void insertQuarter() {  
    // insert quarter code here  
}
```

```
public void ejectQuarter() {  
    // eject quarter code here  
}
```

... but then, you'd have to add a new conditional in every single method to handle the WINNER state; that's a lot of code to modify.

```
public void turnCrank() {  
    // turn crank code here  
}
```

```
public void dispense() {  
    // dispense code here  
}
```

turnCrank() will get especially messy, because you'd have to add code to check to see whether you've got a WINNER and then switch to either the WINNER state or the SOLD state.

Okay, this isn't good. I think our first version was great, but it isn't going to hold up over time as Mighty Gumball keeps asking for new behavior. The rate of bugs is just going to make us look bad, not to mention the CEO will drive us crazy.

Observations ...

We should try to **localize the behavior** for each state so that if we make changes to one state, we don't run the risk of messing up the other code.

If we put each state's behavior in its own class, then **every state just implements its own actions**. The Gumball Machine can just delegate to the state object that represents the current state.

The new design

Now we're going to put all the behavior of a state into one class. That way, we're localizing the behavior and making things a lot easier to change and understand.

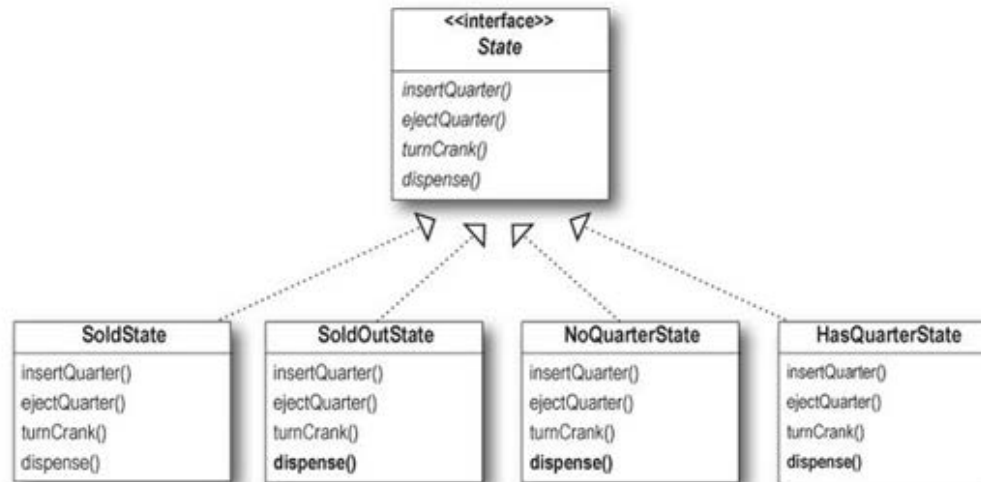

First, we're going to define a State interface that contains a method for every action in the Gumball Machine.

Then we're going to implement a State class for every state of the machine. These classes will be responsible for the behavior of the machine when it is in the corresponding state.

Finally, we're going to get rid of all of our conditional code and instead delegate to the State class to do the work for us.

Defining the State interfaces and classes

To figure out what states we need, we look at our previous code...

```
public class GumballMachine {
```

```
    final static int SOLD_OUT = 0;
    final static int NO_QUARTER = 1;
    final static int HAS_QUARTER = 2;
    final static int SOLD = 3;
```

```
    int state = SOLD_OUT;
    int count = 0;
```

... and we map each state directly to a class.

Don't forget, we need a new "winner" state too that implements the state interface. We'll come back to this after we reimplement the first version of the Gumball Machine.

Implementing our State classes

First we need to implement the State interface.

We get passed a reference to the Gumball Machine through the constructor. We're just going to stash this in an instance variable.

```
public class NoQuarterState implements State {
    GumballMachine gumballMachine;
```

```
    public NoQuarterState(GumballMachine gumballMachine) {
        this.gumballMachine = gumballMachine;
    }
```

If someone inserts a quarter, we print a message saying the quarter was accepted and then change the machine's state to the HasQuarterState.

```
    public void insertQuarter() {
        System.out.println("You inserted a quarter");
        gumballMachine.setState(gumballMachine.getHasQuarterState());
    }
```

You'll see how these work in just a sec...

```
    public void ejectQuarter() {
        System.out.println("You haven't inserted a quarter");
    }
```

You can't get money back if you never gave it to us!

```
    public void turnCrank() {
        System.out.println("You turned, but there's no quarter");
    }
```

And you can't get a gumball if you don't pay us.

```
    public void dispense() {
        System.out.println("You need to pay first");
    }
```

We can't be dispensing gumballs without payment.

```
}
```

Reworking the Gumball Machine

```
public class GumballMachine {  
  
    final static int SOLD_OUT = 0;  
    final static int NO_QUARTER = 1;  
    final static int HAS_QUARTER = 2;  
    final static int SOLD = 3;  
  
    int state = SOLD_OUT;  
    int count = 0;  
}
```

Old code

In the GumballMachine, we update the code to use the new classes rather than the static integers. The code is quite similar, except that in one class we have integers and in the other objects...

```
public class GumballMachine {  
  
    State soldOutState;  
    State noQuarterState;  
    State hasQuarterState;  
    State soldState;  
  
    State state = soldOutState;  
    int count = 0;  
}
```

New code

All the State objects are created and assigned in the constructor.

This now holds a State object, not an integer.

Complete GumballMachine class

```
public class GumballMachine {
```

```
    State soldOutState;  
    State noQuarterState;  
    State hasQuarterState;  
    State soldState;
```

```
    State state;  
    int count = 0;
```

```
    public GumballMachine(int numberGumballs) {  
        soldOutState = new SoldOutState(this);  
        noQuarterState = new NoQuarterState(this);  
        hasQuarterState = new HasQuarterState(this);  
        soldState = new SoldState(this);  
    }
```

```
        this.count = numberGumballs;  
        if (numberGumballs > 0) {  
            state = noQuarterState;  
        } else {  
            state = soldOutState;  
        }  
    }
```

```
    public void insertQuarter() {  
        state.insertQuarter();  
    }
```

```
    public void ejectQuarter() {  
        state.ejectQuarter();  
    }
```

```
    public void turnCrank() {  
        state.turnCrank();  
        state.dispense();  
    }
```

```
    void setState(State state) {  
        this.state = state;  
    }
```

```
    void releaseBall() {  
        System.out.println("A gumball comes rolling out the slot...");  
        if (count != 0) {  
            count = count - 1;  
        }  
    }
```

```
    // More methods here including getters for each State...
```

```
}
```

Here are all the States again...

...and the State instance variable.

The count instance variable holds the count of gumballs - initially the machine is empty.

Our constructor takes the initial number of gumballs and stores it in an instance variable.

It also creates the State instances, one of each.

If there are more than 0 gumballs we set the state to the NoQuarterState; otherwise, we start in the SoldOutState.

Now for the actions. These are VERY EASY to implement now. We just delegate to the current state.

Note that we don't need an action method for dispense() in GumballMachine because it's just an internal action; a user can't ask the machine to dispense directly. But we do call dispense() on the State object from the turnCrank() method.

This method allows other objects (like our State objects) to transition the machine to a different state.

The machine supports a releaseBall() helper method that releases the ball and decrements the count instance variable.

This includes methods like getNoQuarterState() for getting each state object, and getCount() for getting the gumball count.

Coding more states 1/2

```
public class HasQuarterState implements State {
    GumballMachine gumballMachine;
```

When the state is instantiated we pass it a reference to the GumballMachine. This is used to transition the machine to a different state.

```
    public HasQuarterState(GumballMachine gumballMachine) {
        this.gumballMachine = gumballMachine;
    }
```

```
    public void insertQuarter() {
        System.out.println("You can't insert another quarter");
    }
```

An inappropriate action for this state.

```
    public void ejectQuarter() {
        System.out.println("Quarter returned");
        gumballMachine.setState(gumballMachine.getNoQuarterState());
    }
```

Return the customer's quarter and transition back to the NoQuarterState.

```
    public void turnCrank() {
        System.out.println("You turned...");
        gumballMachine.setState(gumballMachine.getSoldState());
    }
```

When the crank is turned we transition the machine to the SoldState state by calling its setState() method and passing it the SoldState object. The SoldState object is retrieved by the getSoldState() getter method (there is one of these getter methods for each state).

```
    public void dispense() {
        System.out.println("No gumball dispensed");
    }
}
```

Another inappropriate action for this state.

Coding more states 2/2

```
public class SoldState implements State {
    //constructor and instance variables here
```

```
    public void insertQuarter() {
        System.out.println("Please wait, we're already giving you a gumball");
    }
```

```
    public void ejectQuarter() {
        System.out.println("Sorry, you already turned the crank");
    }
```

```
    public void turnCrank() {
        System.out.println("Turning twice doesn't get you another gumball!");
    }
```

Here are all the inappropriate actions for this state.

And here's where the real work begins...

```
    public void dispense() {
        gumballMachine.releaseBall();
        if (gumballMachine.getCount() > 0) {
            gumballMachine.setState(gumballMachine.getNoQuarterState());
        } else {
            System.out.println("Oops, out of gumballs!");
            gumballMachine.setState(gumballMachine.getSoldOutState());
        }
    }
}
```

We're in the SoldState, which means the customer paid. So, we first need to ask the machine to release a gumball.

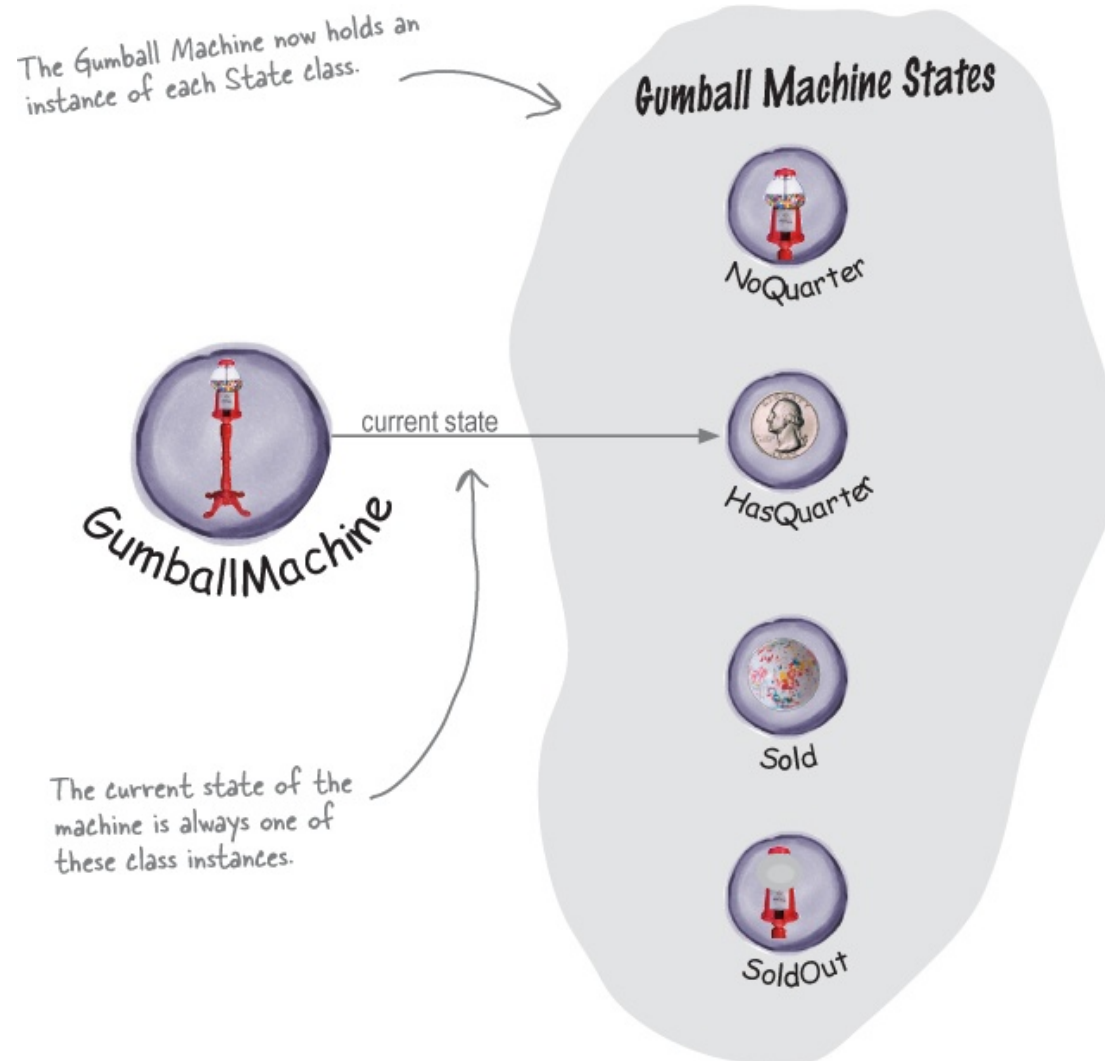

Then we ask the machine what the gumball count is, and either transition to the NoQuarterState or the SoldOutState.

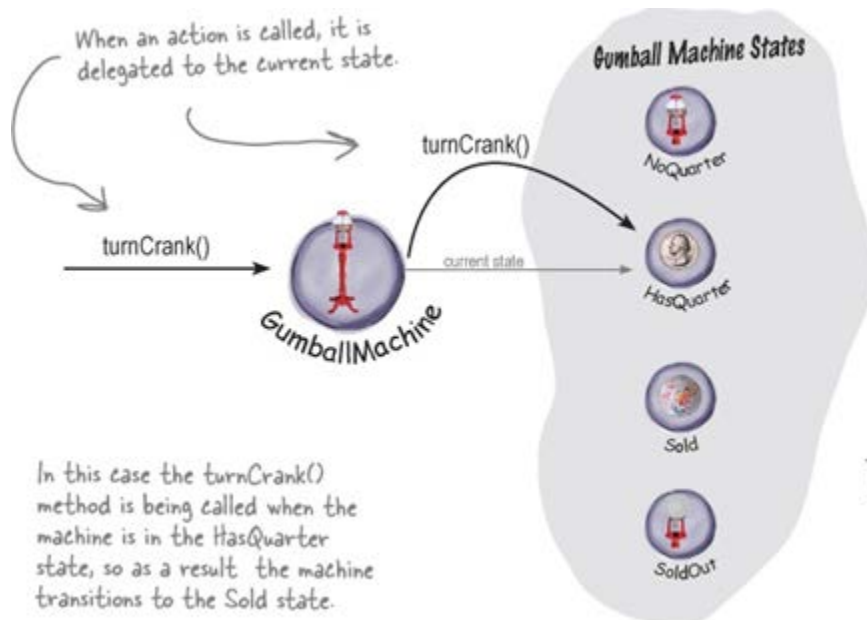

What we have done so far ...

1/2

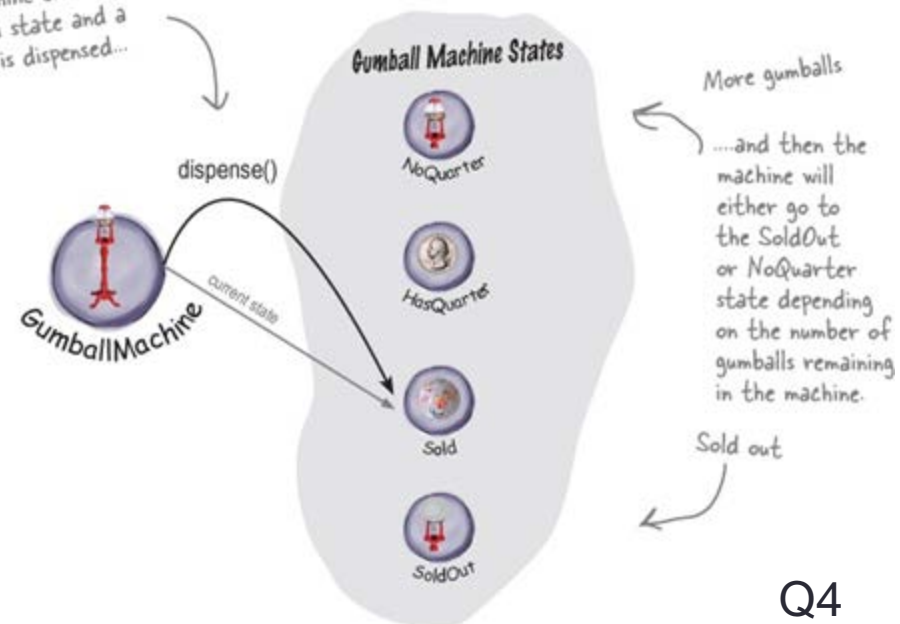

What we have done so far ...

2/2

TRANSITION TO SOLD STATE

The machine enters the Sold state and a gumball is dispensed...

The State Pattern Defined

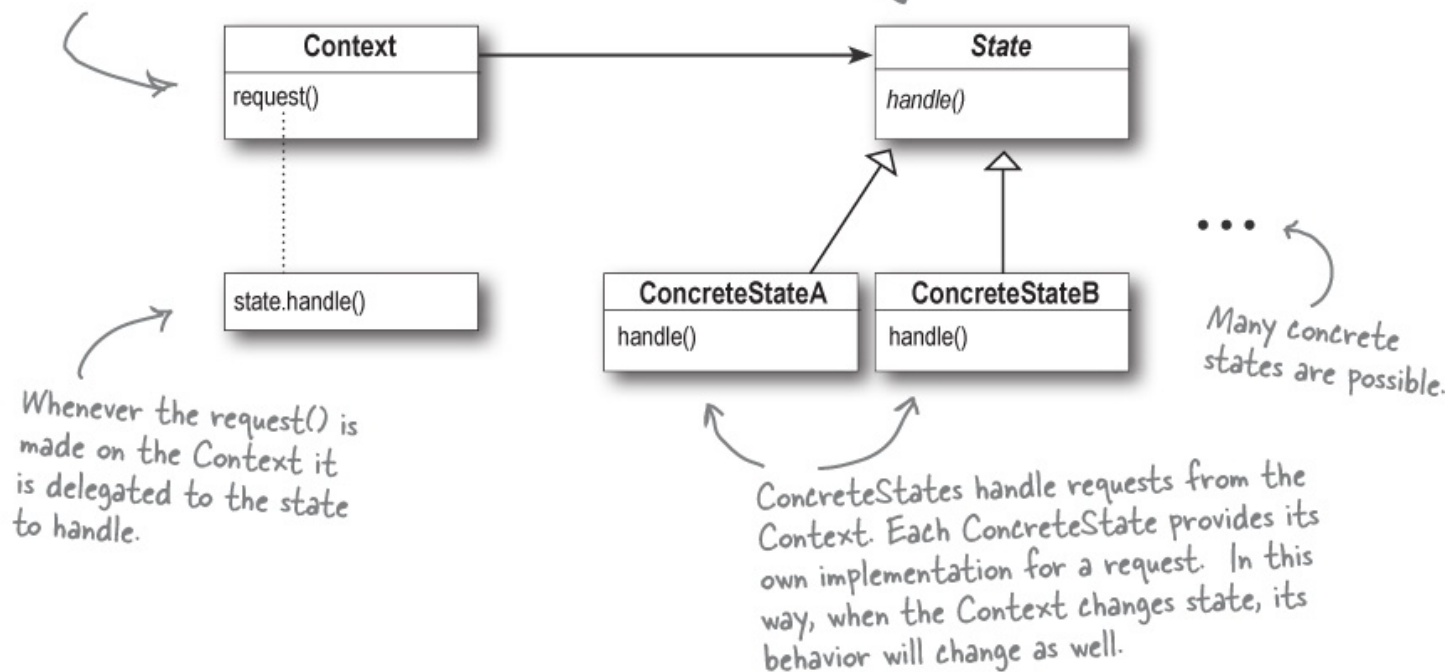

Wait a sec, from what I remember of the Strategy Pattern, this class diagram is EXACTLY the same.

The State Pattern allows an object to alter its behavior when its internal state changes. The object will appear to change its class.

The Context is the class that can have a number of internal states. In our example, the GumballMachine is the Context.

The State interface defines a common interface for all concrete states; the states all implement the same interface, so they are interchangeable.

State vs Strategy

Yes, the class diagrams are essentially the same, but the two patterns differ in their **intent**

With the State Pattern, we have a set of behaviors encapsulated in state objects, but the **client usually knows very little**, if anything, **about the state objects**

With Strategy, the **client usually specifies the strategy object** that the context is composed with

Finish the Gumball 1 in 10 game

```
public class GumballMachine {
```

```
    State soldOutState;  
    State noQuarterState;  
    State hasQuarterState;  
    State soldState;  
    State winnerState;
```

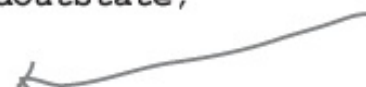

```
    State state = soldOutState;  
    int count = 0;  
    // methods here
```

```
}
```

All you need to add here is the new WinnerState and initialize it in the constructor.

Don't forget you also have to add a getter method for WinnerState too.

Finish the Gumball 1 in 10 game

```
public class WinnerState implements State {
```

```
    // instance variables and constructor
    // insertQuarter error message
    // ejectQuarter error message
    // turnCrank error message
```

Just like SoldState.

Here we release two gumballs and then either go to the NoQuarterState or the SoldOutState.

```
    public void dispense() {
        gumballMachine.releaseBall();
        if (gumballMachine.getCount() == 0) {
            gumballMachine.setState(gumballMachine.getSoldOutState());
        } else {
            gumballMachine.releaseBall();
            System.out.println("YOU'RE A WINNER! You got two gumballs for your quarter");
            if (gumballMachine.getCount() > 0) {
                gumballMachine.setState(gumballMachine.getNoQuarterState());
            } else {
                System.out.println("Oops, out of gumballs!");
                gumballMachine.setState(gumballMachine.getSoldOutState());
            }
        }
    }
}
```

← If we have a second gumball we release it.

← If we were able to release two gumballs, we let the user know he was a winner.

Finishing the Random Chance

```

public class HasQuarterState implements State {
    Random randomWinner = new Random(System.currentTimeMillis());
    GumballMachine gumballMachine;

    public HasQuarterState(GumballMachine gumballMachine) {
        this.gumballMachine = gumballMachine;
    }

    public void insertQuarter() {
        System.out.println("You can't insert another quarter");
    }

    public void ejectQuarter() {
        System.out.println("Quarter returned");
        gumballMachine.setState(gumballMachine.getNoQuarterState());
    }

    public void turnCrank() {
        System.out.println("You turned...");
        int winner = randomWinner.nextInt(10);
        if ((winner == 0) && (gumballMachine.getCount() > 1)) {
            gumballMachine.setState(gumballMachine.getWinnerState());
        } else {
            gumballMachine.setState(gumballMachine.getSoldState());
        }
    }

    public void dispense() {
        System.out.println("No gumball dispensed");
    }
}

```

First we add a random number generator to generate the 10% chance of winning...

...then we determine if this customer won.

If they won, and there's enough gumballs left for them to get two, we go to the WinnerState; otherwise, we go to the SoldState (just like we always did).

Demo for the CEO of Mighty Gumball, Inc

`public class GumballMachineTestDrive {`

`public static void main(String[] args) {`

`GumballMachine gumballMachine = new GumballMachine(5);`

`System.out.println(gumballMachine);`

`gumballMachine.insertQuarter();`

`gumballMachine.turnCrank();`

`System.out.println(gumballMachine);`

`gumballMachine.insertQuarter();`

`gumballMachine.turnCrank();`

`gumballMachine.insertQuarter();`

`gumballMachine.turnCrank();`

`System.out.println(gumballMachine);`

`}`

`}`

This code really hasn't changed at all;
we just shortened it a bit.

Once, again, start with a gumball
machine with 5 gumballs.

We want to get a winning state,
so we just keep pumping in those
quarters and turning the crank. We
print out the state of the gumball
machine every so often...

Recap

State allows an object to have many **different behaviors** that are based on its **internal state**.

The Context gets its behavior by **delegating to the current state object** it is composed with.

The State and Strategy Patterns have the same class diagram, but they **differ in intent**.

Using the State Pattern will typically result in a **greater number of classes** in your design.
